LIST OF APPENDICES

EXECUTIVE SUMMARY

Strategic Engineering & Science, Inc. (SES) has performed water quality evaluations for the Permanente Quarry (Quarry), as requested by Lehigh Southwest Cement Company (Lehigh). Lehigh seeks to amend its current reclamation plan and obtain a conditional use permit to support mining and reclamation activities over an estimated 20-year period (Project). The Project would simultaneously develop a new limestone quarry, known as the South Quarry, while reclaiming the existing North Quarry. This report describes the Project's anticipated effects on water quality.

This report considers and benefits from a substantial amount of data. This includes environmental monitoring of surface water at gauging stations both in Permanente Creek and Monte Bello Creek over the past two years, in addition to groundwater results from on-site monitoring wells. This data also includes water testing of existing North Quarry pit water quality, and runoff from mining areas and overburden storage areas. The results of bioassay (fish toxicity) testing of background and baseline surface water quality are also considered.

This report concludes that implementation of the Project will result in significant improvements in water quality in Permanente Creek compared to baseline conditions and it also concludes that water quality will not be affected in Monte Bello Creek.

The table below shows the Project's projected effect on water quality for selected constituents in the North and South Quarry before being discharged into Permanente Creek.

Constituent	North Quarry		South Quarry	
	Existing	After Reclamation	Start of Mining	After Reclamation
Antimony (µg/L)	8.2	1.5 - 2.0	0.2 - 1.0	0.3 - 0.4
Arsenic (µg/L)	4.5	2.5 - 3.0	0.8 - 2.2	2 - 3
Cadmium (µg/L)	0.53	0.15 - 0.20	0.05 -0.1	0.15 - 0.20
Copper (µg/L)	1.5	1.5 - 1.6	1 - 1.2	1.6 - 1.7
Manganese (µg/L)	21	15 - 20	0 - 10	0 - 10
Molybdenum (µg/L)	540	85 - 100	19 - 21	10 - 11
Nickel (µg/L)	160	20 - 30	4 - 5	3 - 4
Selenium (µg/L)	82	10 - 15	8 - 12	1 - 2
TDS (mg/L)	790	500 - 600	400 - 600	500 - 600
Sulfate (mg/L)	550	100 - 200	100 - 140	120 - 140

Existing water quality (or "baseline" water quality) in Permanente Creek is generally good with some exceptions. North Quarry mining operations appear to have increased the concentrations of some constituents above natural background levels in water collected in the quarry and potentially in Permanente Creek. Certain constituents, including selenium, nickel, TDS (Total Dissolved Solids), sulfate, antimony, cadmium, arsenic, manganese, molybdenum, and copper, currently show small to moderate increases above background

levels. Manganese concentrations in the North Quarry are believed to be due to a dynamic condition, as typically oxygenated surface waters do not contain much manganese. Therefore, manganese concentrations are expected to decrease significantly before quarry water is discharged to Permanente Creek. Study and bioassay testing of surface waters in Permanente Creek also indicate that fish and benthic organisms are present and are not detrimentally affected by existing water quality.

The Project would improve upon baseline water quality. The primary mechanism for achieving this improvement is the proposed backfilling and reclamation of the North Quarry. Since limestone rock is the major source of the dissolved constituents in water, backfilling would eliminate most current effects of mining by covering areas of limestone rock exposure and by ensuring future surface runoff only occurs from vegetated topsoil or non-limestone rock types. Groundwater quality within the reclaimed North Quarry would also improve as limestone exposures are covered and flooded by surface water inflow and groundwater recharge.

Good water management practices in the South Quarry will complement North Quarry reclamation. As summarized in the report below, all constituents are expected to be at or within regulatory water quality benchmarks after reclamation, including all federal drinking water standards. In particular, selenium concentrations are projected to decrease by 80 percent or more during reclamation.

SES recommends that the Project include a monitoring and verification program during mining and reclamation in order to verify water quality under field conditions. SES also recommends materials handling procedures to assure maximum protection of surface water quality. Such procedures would provide for good drainage around disturbed limestone areas and stockpiles to minimize contact with rainfall and runoff. Additional recommendations and considerations are included in the body of this report.

1.0 INTRODUCTION

This report describes the results of the water quality evaluations performed for the amendment to the reclamation plan and conditional use permit application for the Permanente Quarry (Project) in Santa Clara County, California (see Project Area, Figure 1). This report provides future water quality projections for flows into the North Quarry and the South Quarry and runoff from the reclaimed quarry areas, and provides recommendations for backfilling and reclamation that enhance water quality.

More specifically, this report addresses:

- Background and baseline water quality at the Project
- Projections of mine water quality during mine backfilling and reclamation
- Projections of runoff water quality during and after reclamation
- Recommended verification monitoring program
- Recommended mined materials and overburden handling procedures

2.0 BACKGROUND

2.1 Existing Operations

The Permanente Quarry (Quarry) is a limestone and aggregate mining operation in the unincorporated foothills of western Santa Clara County, approximately two miles west of the City of Cupertino. The Quarry occupies a portion of a 3,510-acre property owned by Hanson Permanente Cement, Inc., and is operated by Lehigh Southwest Cement Company (collectively, Lehigh).

The Quarry currently comprises approximately 537 acres of operational areas, which consist of surface mining excavations, overburden stockpiling, crushing and processing facilities, access roads, administrative offices, and equipment storage. The Quarry also includes other predominantly undisturbed areas, either held in reserve for future mining or which buffer operations from adjacent land uses. The main operational areas of the Quarry are currently as follows:

- North Quarry: The North Quarry is where mineral extraction currently occurs and has historically taken place. The North Quarry features a large mining pit with elevations that currently range from approximately 750 feet to 1,750 feet above mean sea level (amsl). Limestone and greenstone mined from the North Quarry

are crushed and either processed into aggregate products at Lehigh's on-site Rock Plant or used for cement manufacture at Lehigh's adjacent cement plant. Historically, the North Quarry has filled with water to an approximate elevation of 775 feet amsl except when it is actively dewatered for mining. At present, mining occurs in the North Quarry on the south and west walls above an elevation of 800 feet amsl.

- East Materials Storage Area (EMSA): The EMSA is located to the east of the North Quarry and is currently the primary storage site for overburden. Elevations at the EMSA range from 550 to 920 feet amsl.

- West Materials Storage Area (WMSA): The WMSA is a second overburden storage site, located west of the North Quarry. Elevations in the WMSA range from 1,500 to 1,975 feet amsl. The WMSA is approaching the final elevation and contours, described in the Quarry's existing reclamation plan.

- Rock Plant: The Rock Plant is located in the southeast portion of the Quarry, and processes mined material into aggregate products. The Rock Plant occupies gentle slopes ranging from 580 and 770 feet amsl.

Mining operations take place subject to California's Surface Mining and Reclamation Act (SMARA). SMARA mandates that surface mining operations have an approved reclamation plan that describes how mined lands will be prepared for alternative post-mining uses, and how residual hazards will be addressed. Santa Clara County acts as lead agency under SMARA. The County approved the Quarry's current reclamation plan in March 1985, covering 330 acres.

Lehigh excavates limestone from the Quarry for the production of cement and aggregate. Limestone that is of suitable grade is used for cement production; lower grade limestone is used for aggregate. Unsuitable rock materials (overburden) excavated from the Quarry are permanently stockpiled in the WMSA or EMSA. Overburden materials are comprised of non-limestone rock materials (i.e., greenstones, metabasalts, and graywacke) and some minor amounts of low-grade limestone not suitable for use as aggregate.

A cement manufacturing plant lies adjacent to the Quarry in the east. The cement plant also is owned and operated by Lehigh. The cement plant is separately permitted for industrial use and is not considered part of the Quarry and therefore, is not subject to SMARA's requirements.

2.2 Proposed Project

The proposed Project is the approval of an amendment to the Quarry's reclamation plan. The proposed amendment would broaden the reclamation plan and associated reclamation requirements to include all areas that are currently disturbed by mining activities, including lands scheduled to be disturbed by mining over approximately the next 20 years. The

amendment would provide for the reclamation of existing and planned mining disturbance within 1,105 acres of Lehigh's 3,510-acre ownership over a period of approximately the next 20 years. Under the amendment, areas disturbed by mining would be reclaimed for open space uses.

The Project also includes the approval of a Conditional Use Permit (CUP) for certain mining operations at the Quarry. The CUP would authorize the continuation of mineral extraction in a portion of the planned extraction area south of Permanente Creek, known as the South Quarry. Rock mined at the South Quarry would be transported to existing facilities for processing. The South Quarry is included in the proposed reclamation plan amendment and would be reclaimed according to the requirements therein.

The Project would result in the following conditions and changes at the Quarry:

- South Quarry: The Project would approve a CUP and amend the reclamation plan to provide for concurrent mining and reclamation at the South Quarry. The South Quarry will be developed in five phases over a period of about 20 years, depending on market demand. The approximate pit limits are shown in Figure 2. Reclamation would follow mining within each phase. Mined limestone and greenstone would be transported to existing Quarry facilities for crushing and processing. The ultimate floor in the east half of the South Quarry will be at an elevation of 925 feet amsl, approximately 150 feet below Permanente Creek. During reclamation, the lower benches of the pit will be backfilled to an elevation of 1110-1120 feet amsl, above the level of Permanente Creek.

- Topsoil Storage Area: The Project would amend the reclamation plan to provide for the reclamation of the Topsoil Storage Area, located to the south of the Rock Plant. The Topsoil Storage Area would serve to temporarily store topsoil material removed from the South Quarry until such material is needed for reclamation.

- North Quarry: The Project would amend the current reclamation plan for the North Quarry to reflect the use of the North Quarry as a permanent storage site for overburden extracted from the South Quarry. Reclamation will backfill the North Quarry floor to a minimum elevation of 990 feet amsl. The final phases of reclamation will create new walls along the full depth of the south, southwest, and east sides of the North Quarry pit. Reclamation activities would establish final slope contours and vegetation consistent with the surrounding topography.

- Central Materials Storage Area (CMSA): The Project would amend the reclamation plan to include the CMSA, an overburden storage site located directly west of the EMSA and east of the North Quarry in elevations ranging from 775 to 1270 amsl. The proposed reclamation plan amendment would provide final grading contours and re-vegetation for this area.

- EMSA: Reclamation for the EMSA was provided for in the reclamation plan amendment for the East Materials Storage Area, submitted in April 2009. The EMSA is expected to be in active reclamation at the time of Project approval.

- WMSA: The Project would amend the current reclamation plan for the WMSA to reflect the transition of the adjacent North Quarry reclaimed fill slopes and tie in these slopes to the WMSA's east side. The project also would update the current WMSA re-vegetation design.

- Rock Plant: The Project would amend the reclamation plan to provide a reclamation design for the Rock Plant.

3.0 SURFACE WATER QUALITY

This section describes the hydrology and water quality in the drainage basins in the Project Area and compares data against standards for surface water as established by the Regional Water Quality Control Board (RWQCB) in the current Basin Plan Benchmarks (Benchmarks). This section discusses background (i.e. surface water up-gradient from existing mining areas) and baseline water quality (i.e. adjacent to and downstream from existing mining areas). The Benchmarks, background and baseline conditions serve as a basis of comparison that can be used to evaluate whether future mining activities could result in any water quality impacts. These data are not intended to determine how regulated discharges from current operations affect Permanente Creek water quality compared to regulatory standards. Factors necessary for such a determination, including the hardness of Permanente Creek water and background water quality, have not been fully analyzed in this report.

3.1 Hydrology

The area surrounding the Project Area is drained by Permanente Creek, as well as by Monte Bello Creek which is located in the Stevens Creek Basin. Water quality sampling has taken place at two gauges on Permanente Creek; SW-1, located adjacent to the most western edge of the existing mining operations and SW-2, located downstream from the operations. Sampling is conducted at one gauge on Monte Bello Creek at SW-3, which is unaffected by any of the existing operations.

The catchment areas draining to the above three sampling stations are (Golder, 2010b):

SW-1 662 acres

SW-2 1,707 acres

SW-3 419 acres

Streamflow is generally intermittent and increases rapidly during rainfall events. Flows in Permanente Creek between SW-1 and SW-2 may be reduced by infiltration from the Creek to the North Quarry. The North Quarry bottom is currently approximately 250 feet below the creek bottom (Golder, 2010b). Flows at SW-2 are augmented by water pumped out of the North Quarry on a routine basis to maintain conditions suitable for mining. Water that accumulates in the North Quarry comes from rainfall onto the quarry walls, stormwater runoff from surrounding areas, and from groundwater inflow.

3.2 Water Quality Benchmarks

This report provides an analysis of existing and projected water quality against certain regulatory standards. Potentially applicable standards are defined by the San Francisco Bay RWQCB. The RWQCB regulates water quality based on the intended uses of water. These uses, known as beneficial uses, guide what water quality standards apply to a given water body.

The designated beneficial uses of surface water for Permanente Creek include cold freshwater habitat (COLD), fishing spawning (SPAWN), wildlife (WILD), water contact recreation (REC 1) and non-contact water recreation (REC 2) (San Francisco Area Basin Plan, RWQCB, 2007). Specific numeric Benchmarks have been established for certain metals including arsenic, cadmium, chromium, copper, lead, mercury, selenium, silver, and zinc. These are listed on Table 1, although they have not yet been adjusted to reflect the hardness of the water as called for in the Basin Plan. Generally, these Benchmarks have been derived for the protection of aquatic habitat.

For some water bodies, the RWQCB also applies human drinking water quality standards. The US Environmental Protection Agency (EPA) has established Maximum Contaminant Levels (MCLs) for drinking water, defined as the maximum permissible level of a contaminant in water delivered to a user of a public water system. The RWQCB incorporates these standards where water is designated for municipal use and is meant for human consumption.

In Permanente Creek, surface waters are designated for the protection of aquatic habitat and are not designated for human consumption. Nonetheless, federal drinking water MCLs have been presented in this report as Benchmarks for comparison purposes.

3.3 Background Water Quality

SW-1 in Permanente Creek is not completely upstream of all quarry activities as it is adjacent to the WMSA. Nonetheless, water quality is comparable to SW-3, on the adjacent Monte Bello Creek, for most metals. SW-1 is therefore considered to be unimpacted by mining for these constituents. In contrast, total dissolved solids (TDS), sulfate, iron and selenium at SW-1 are elevated compared to SW-3, indicating that mining activities may be having some impact. While surface flow at station SW-3 in Monte Bello Creek is useful in characterizing background quality for the general area around the Project, it may not be completely representative of background in Permanente Creek. Permanente Creek likely has more naturally occurring mineralized rock outcrops that could be causing increased concentrations of constituents in background water.

Samples were collected at SW-1 and SW-3 in February, April and September 2009 and in January 2010. The results of analyses for dissolved constituents in these waters are provided in Table 1. Surface water at the "background stations" SW-1 and SW-3 meets the Benchmarks, with the exception of TDS and selenium[1].

3.4 Baseline Water Quality

Baseline water quality was established at SW-2 using samples collected at the same time period as the background samples. The results are summarized on Table 2.

Baseline surface water quality generally meets the Benchmarks, with the exception of TDS, nickel and selenium. Dissolved selenium concentrations are contained in background Permanente Creek water and the water collected in the North Quarry. At SW-2, selenium concentrations have ranged from 13 to 81 µg/L at SW-2. North Quarry water sampled in January 2010 had a dissolved selenium concentration of 82 µg/L (Golder, 2010b). Nickel concentrations may not exceed the Benchmarks depending on the hardness of the water.

There is one isolated exception for mercury, which at 0.07 µg/L is not significantly above the 0.025 µg/L, 4-day average goal and is below the 2.4 µg/L one-hour goal. Mercury occurs naturally in the various rock types and is detected in groundwater which is not affected by mining (Table 3).

Waste screen bio-analyses were conducted on water collected at SW-2 in February and April 2009 using fathead Minnows (Pimepholes Primelas). These tests demonstrated that the

[1] The one elevated concentration of mercury is likely due to natural conditions.

selenium exceedances had no effect on fish mortality. All tests had a 100% survival rate. Furthermore, biologists familiar with this area of Permanente Creek have concluded that fish and benthic diversity and abundance in the downstream reaches of the creek are similar to the upper reaches above SW-1 (WRA, 2010).

Comparing the baseline to the background concentrations (Tables 1 and 2) indicates that there are increases in the concentrations of TDS and sulfate (when compared to SW-3), as well as antimony, arsenic, cadmium, manganese, molybdenum, nickel and selenium (when compared to SW-3). However, as mentioned above, with the exception of TDS and selenium, these concentrations do not exceed the Benchmark levels. Data on the hardness of the water would be necessary to determine whether nickel exceeds Benchmark levels.

4.0 GROUNDWATER QUALITY

In addition to characterizing the background water quality, this section briefly describes the geohydrology of the Quarry area and the applicable Benchmarks used for evaluating groundwater quality. The Benchmarks and background conditions serve as a basis of comparison that can be used to evaluate whether future mining activities have any water quality impacts.

4.1 Geohydrology

Groundwater in the area typically occurs in fractured bedrock of relatively low permeability. In 2007, the water level in the North Quarry was at an elevation of approximately 754 feet amsl, which correlates well with the likely static groundwater level of approximately 775 feet amsl based on groundwater occurrence in exploratory borings, the location of groundwater seepage within the quarry walls, and the location of the adjacent Permanente Creek (Golder, 2010a). The creek may be hydraulically connected to the North Quarry as suggested by a dry creek bed adjacent to the pit, while surface water flows occur both upstream of and downstream from the North Quarry (Golder, 2010b).

Groundwater seepage was observed during May and June 2007 on a wide bench at approximate elevation of 1,050 feet amsl in the southwest corner of the North Quarry. These observations support the concept of localized groundwater occurrence in the greenstone above the regional static groundwater level due to its low permeability.

4.2 Water Quality Benchmarks

The beneficial uses of groundwater in the Quarry area include Drinking (potable) Water (MUN) and agricultural usage (AGR) (RWQCB, 2007). Specific numeric Benchmarks have also been established by the US EPA and the California EPA. Applicable Benchmarks are listed on Table 3.

4.3 Water Quality

Groundwater sampling was conducted in February, April and October 2009 and January 2010 at five monitoring wells (HG-4, -6, -7, -9, and -10 on Figure 2) (Golder, 2010b). These wells are located in the general area where the future South Quarry is to be located. The results for dissolved metals are provided in Table 3.

Groundwater quality generally meets the Benchmarks with the exception of TDS, sulfate, iron, manganese and molybdenum (Table 3). These five constituents are naturally elevated in groundwater due to the mineralized nature of the bedrock.

5.0 OVERBURDEN CHARACTERIZATION

This section discusses the amount and geologic types of overburden that is expected to be generated during future mining and summarizes the testing conducted on mined material and overburden. These tests were conducted to characterize the potential future water quality impacts associated with the overburden and various mined materials. These results are used in Section 6.0 to project future water quality in the quarries.

5.1 Overburden and Backfill Production Schedule

Over an approximate 20-year Project period, Lehigh is expected to mine the following quantities of product from the South Quarry:

Limestone (for cement):	28.6 million tons
Aggregate production:	36.8 million tons
Aggregate fines:	7.5 million tons

As not all the material that is mined is usable, the following quantities of topsoil and overburden will be generated:

Topsoil (Salvaged for future use)	1.3 million tons
Overburden rock (unmarketable material)	108.3 million tons

Comparing the geologic maps and the mine plans (Appendix A) indicates that overburden will consist of the following rock types:

Greenstone:	35%
Graywacke:	20%
Fault Breccia:	45%

The overburden will be disposed of at the following facilities in the following percentages:

Western Materials Storage Area:	4%
Eastern Materials Storage Area:	5%
Within North Quarry:	88%
Within South Quarry:	3%

Table 4 provides more details on the Quarry backfill volumes and rock types.

5.2 Mined Material and Overburden Geochemistry

Several different types of tests were conducted on the mined material present in the quarries and on the overburden that will be removed in the future. These tests included determining the total metals content and the leachability of general minerals and metals from these materials. Leachability was determined using the Modified California Assessment Manual Waste Extraction Test (CAM WET) and wall washing tests. In addition, North Quarry water runoff from the WMSA was analyzed for general minerals and metals. Finally, acid-base accounting testing was done to confirm that the materials do not have any acid generating potential. Details are contained in the Hydrologic Investigation Report (Golder, 2010b).

This information, together with the data provided in Section 4.3 (Baseline Groundwater Quality), is used in Section 6.0 to determine water quality during future mining activities.

5.2.1 Total Metals

Table 5 provides the total concentrations determined from rock boring samples collected in both the North Quarry and the South Quarry, either as composited or individual samples. Rock types are also indicated in the Table and include the various overburden rock types and limestone which is a mined material (product).

5.2.2 Modified CAM WET Results

CAM WET tests were conducted using de-ionized water. These tests indicate that the mined material (limestone) contains low levels of leachable molybdenum and selenium. The overburden materials such as graywacke, fault breccia, greenstone, metabasalt and chert have lower leachability for molybdenum and a very limited selenium leachability.

5.2.3 Wall Washing

Wall washing tests were performed on exposed faces within the North Quarry in 2009 (Golder, 2010b). These tests involved washing an approximately one-meter square area of rock face with a known volume of water. The resultant wash water was analyzed for dissolved and total metal concentrations and general minerals. The results are provided in Table 7.

These wall washing samples provide an indication as to the amount of dissolved constituents that could be leached out during a rainstorm for the various rock types. The amount of wash water added was approximately equivalent to a 0.25 inch rainstorm event.

5.2.4 Project Water Quality Sampling

Water samples were collected on January 13, 2010 from the water stored in the North Quarry and from runoff from the WMSA. The resultant constituent concentrations are provided in Table 7. The North Quarry sample provides evidence of the typical water quality that is currently entering the quarry by runoff from surrounding areas, the quarry walls, and groundwater.

5.2.5 Acid Generating Potential

The major rock types found in the quarries were tested for acid-generating potential. These included graywacke, limestone, chert, fault breccia, greenstone and metabasalt. All were found to have no potential for acid generation (Golder, 2010b). The ratio of neutralization potential to acid generation potential ranged from four for fault breccia, to the hundreds and thousands for greenstone and metabasalt. Typically, a ratio of greater than three (Hutchison et. al., 1992) indicates there is no acid generating potential.

Net neutralization capacity, i.e. the difference between the rock's neutralization capacity and its acid generating capacity range from 58 Kg (calcium carbonate equivalent – $CaCO_3$) per ton for graywacke to 867 Kg (calcium carbonate equivalent - $CaCO_3$)/t for metabasalt. Typically, values above 20 Kg ($CaCO_3$)/t are considered non-acid generating (Hutchison et. al., 1992).

6.0 WATER QUALITY DURING FUTURE MINING

This section describes the mining and reclamation plans under the Project for the North Quarry and the South Quarry and the rate at which backfilling of the quarries will occur (Section 6.1). Further, it discusses the water balance associated with each during the reclamation period (Section 6.2), describes the expected rates the quarries will fill with water, provides projected future quarry water quality during operations as well as during the reclamation and post-reclamation periods (Section 6.3). These projections are not intended to determine how the resulting Permanente Creek water quality would compare to regulatory standards when water from quarry operations is discharged to Permanente Creek. Factors necessary for such a determination, including the hardness of Permanente Creek water and background water quality, have not been fully analyzed

The water quality projections described in this section are for the North Quarry and the South Quarry that are located within the Permanente Creek's drainage basin. A small portion of the South Quarry will be located in the Monte Bello Creek drainage basin. This is not expected to result in any water quality changes in Monte Bello Creek. All other drainage within the South Quarry will be controlled to flow towards Permanente Creek.

6.1 Quarry Reclamation Plan

After mining ceases, the North Quarry and South Quarry will be reclaimed by backfilling the mining excavations to a specified level. Backfilled areas will be allowed to fill with surface water runoff and infiltrating groundwater. The backfill in each quarry has been designed to ensure that the surface of the backfill will remain above the maximum elevation of the water that accumulates in each quarry, thereby avoiding surface impoundments. Each drainage system will be established with a positive sloping gradient in order to convey excess surface water to Permanente Creek.

Mining and reclamation are planned under five phases. Details of these plans and the various drainage areas discussed below are contained in Appendices B and C. Section 7.0 describes a proposed verification monitoring program that will provide the necessary data to establish whether drainage plan refinements will be necessary.

6.1.1 Inflow to North Quarry

(a) Existing Conditions

The following surfaces drain into North Quarry (including all WMSA haul roads):

Un-reclaimed WMSA:	83 acres
Quarry Walls: greenstone and graywacke	112 acres
Quarry Walls: limestone	161 acres
Total:	**356 acres**

(b) Phase 1

North Quarry will be mined to an elevation of approximately 440 feet amsl. During this period, limestone product will be recovered and overburden rock comprised of greenstone, graywacke and chert will be placed on the west wall of the North Quarry.

At the end of Phase I the following areas will drain into the North Quarry:

Un-reclaimed WMSA:	42 acres
Reclaimed WMSA:	41 acres
Quarry Walls: greenstone and graywacke	112 acres
Quarry Walls: limestone	161 acres
Total:	**356 acres**

At this stage it is assumed that 50% of the WMSA will be reclaimed and runoff from its surface discharged as stormwater to Permanente Creek.

(c) Phase 2

During Phase 2, the North Quarry backfilling will commence. Breccia (including greenstone) and graywacke overburden from the South Quarry will be placed in the North Quarry, which will be backfilled to an elevation of approximately 840 feet amsl.

At the end of Phase 2, the following areas will drain into the partially backfilled North Quarry:

Reclaimed WMSA:	83 acres
Quarry Walls: greenstone and graywacke	124 acres
Quarry Walls: limestone	110 acres
Backfilled North Quarry Area (greenstone and graywacke)	41 acres
Total:	**358 acres**

(d) Phase 3

During Phase 3, backfilling of the North Quarry bottom will be completed to an approximate elevation of 990 feet amsl. Water will progressively accumulate in the backfill via groundwater inflow and surface infiltration through the 18-acre backfill surface (Section 6.2).

(e) Phases 4 and 5

The same conditions apply as in Phase 3.

6.1.2 Runoff from North Quarry

During the initial reclamation phase and through the end of Phase 3, rainfall runoff generated inside the North Quarry will flow into the quarry bottom where it will accumulate or be pumped out. The water will be pumped out during the active mining period. For purposes of this analysis, it is assumed that water will also be pumped out for the first year of Phase 2 when backfilling starts and effective water management procedures for the backfilling period will be established. Thereafter, water will be pumped as necessary to maintain a dry work surface, and otherwise allowed to accumulate as groundwater within the backfill subsurface.

For purposes of determining the amount and quality of the surface water runoff from the North Quarry to Permanente Creek after the backfill reaches its maximum level, the following drainage areas were determined for the end of each of the following phases:

Phase	Quarry Walls (acres)		Total (acres)
	Covered	Exposed	
	Breccia & Greenstone[1]	Limestone	
3	269	89[1]	358
4	294	64[2]	358
5	333	4[3]	337[4]

(1) Includes the 83-acre reclaimed WMSA.
(2) Includes 42 acres of unspecified rock that is conservatively assumed to be limestone (Appendix B).
(3) Includes 6 acres of unspecified rock that is conservatively assumed to be limestone (Appendix B).
(4) The area to the north-east of the WMSA will be reclaimed and drained separately to the north.

6.1.3 Inflow to South Quarry

Mining in the South Quarry is expected to commence during Phase 1 with overburden being hauled for disposal to the CMSA and the North Quarry. The final anticipated elevation of mining is approximately 925 ft amsl. Backfilling is expected to occur during Phase 5 to a minimum elevation of 1,110 feet amsl. The drainage areas below apply to the western portion of the South Quarry development that includes the deepest portion of the South Quarry excavation. The eastern portion includes haul roads and does not contain any mining other than the grading needed for road construction, therefore it is not considered in these analyses.

Mining in the South Quarry from Phases 1 through 3 occurs on the north facing hillside and would not result, in this stage, in a developed “pit” that would accumulate water. Surface water runoff from the mined areas will occur and is discussed in Section 6.1.4 below.

During Phases 3 through 5 of mining, a pit will develop in South Quarry. The areas that drain into this pit are described below.

(a) Phase 4A

Quarry Walls:	breccia and graywacke	14 acres
Quarry Walls:	limestone	6 acres
Total:		**20 acres**

(b) Phase 4B

Quarry Walls:	breccia and graywacke	16 acres
Quarry Walls:	limestone	11 acres
Total:		**27 acres**

At the end of Phase 5, the quarry will be backfilled to a minimum elevation of 1,110 feet amsl. At this stage, the inflow to the quarry will be the infiltration through the surface of the backfill and groundwater.

(c) Phase 5

Backfilled South Quarry Area:	breccia and graywacke	13 acres

6.1.4 Runoff from South Quarry

Through all phases of mining and reclamation, runoff will occur from the South Quarry area. This runoff is captured in sediment basins (Chang, 2010) before being discharged.

The following drainage areas occur at the end of each phase:

Phase	Quarry Walls (acres)			Total (acres)
	Natural Terrain	Breccia & Graywacke	Limestone	
1	55	-	35	90
2	13	53	41	107
3	-	85	48	133
4A	-	106	32	138

6.2 Quarry Water Balances

Water balance computations have been completed for the North Quarry and the South Quarry for all phases of mining, reclamation, and post-reclamation, typically for a period of 30 years, i.e. 10 years beyond the end of the Project period.

The drainage areas described in Section 6.1, coupled with average monthly precipitation values, were used to determine the volumes of water over time. The following runoff and infiltration coefficients were used to calculate volumes of water flowing into the North Quarry and South Quarry, plus the direct runoff to Permanente Creek from the surface of the operating and reclaimed South Quarry and the reclaimed North Quarry:

North Quarry Parameters and Coefficients

Mean annual rainfall (Golder, 2010b):	22.2 inches
Runoff from WMSA as a percentage of rainfall (typical surface runoff in area):	30%
Runoff from quarry walls (typical):	50%
Infiltration through surface of backfilled quarry before it can be drained:	50%
Infiltration through surface of backfilled quarry after it is drained (reclamation period):	15%

South Quarry Parameters and Coefficients

Mean annual rainfall (Golder, 2010b):	24.6 inches
Runoff from quarry walls as a percentage of rainfall(typical):	50%
Infiltration through backfilled quarry:	15%

Groundwater inflow is also included in the water balance. Based on groundwater modeling (Golder, 2010b), the following average annual rates of groundwater inflow to the quarries were established and used in the water balance calculations:

North Quarry:	Full Mining Depth (440 feet amsl)	371 gpm inflow
	Approximate final groundwater level in quarry (990 feet amsl)	80 gpm inflow
South Quarry:	Full Mining Depth (925 feet amsl)	90 gpm inflow
	Approximate final groundwater level in quarry (1110 feet amsl)	10 gpm inflow

The above information was utilized in spreadsheet calculations to assess the rate of backfilling with overburden and the average rate of water accumulation in the quarries, as well as to determine the average annual outflow from the quarries after the equilibrium water elevation is reached. The Project provides for sufficient backfill being placed to cover the

water accumulation, particularly during the post-reclamation period. The outflow will be engineered to occur as subsurface flow.

The result of the water balance calculations indicates that the average annual outflows from the quarries will be as follows:

North Quarry: 90 gpm

South Quarry: 30 gpm

Spreadsheet models were used to determine monthly inflows to the quarry and runoff from the quarry areas for a 20-year period, starting with Phase 1. Once backfill starts in a quarry, the models calculated the rate of filling and determined the long-term net outflow. These monthly water balance computations were customized for this project.

The above approach is based on measured climatic conditions, factors based on measurements, professional judgment, and modeling. As such there are uncertainties in the groundwater filling rate, the projected equilibrium levels, and outflows. To account for these uncertainties, verification monitoring, water management measures, and contingencies are recommended for the mine operating period. These are discussed in Section 7.0 below.

The projected quarry backfill and water filling rates are provided in Figures 5 and 6. It is estimated to take approximately 14 and five years to fill the North Quarry and the South Quarry respectively.

6.3 Water Quality Projections

This section describes the water quality projections undertaken for the North Quarry and South Quarry. These projections are based on the water balance spreadsheet models described in Section 6.2, coupled with the water quality testing and sampling data for the mined and overburden materials presented in Section 5.2. The water quality parameters have been specifically selected from the testing results and water quality monitoring to reflect the changing conditions during mining, backfilling, and reclamation. The model assumes that the constituents behave conservatively and there are no geochemical interactions with the adjacent rock materials. For all constituents except manganese, these are considered reasonable assumptions for projecting future conditions.

The projected manganese concentrations are likely over-estimates as manganese is expected to precipitate in the quarries. Dissolved manganese derived from groundwater and weathering becomes oxidized, and as oxidized manganese is not soluble, it precipitates in the quarry water. The water quality input parameters and results for each quarry are discussed in Sections 6.3.1 and 6.3.2 below.

The quarry water quality projections were performed for the following list of dissolved metal constituents:

- Antimony
- Arsenic
- Cadmium
- Copper
- Manganese
- Molybdenum
- Nickel
- Selenium
- TDS
- Sulfate (SO_4)

The North Quarry, which has been eroding and weathering for a long period of time, has predominantly limestone walls. Therefore, the projections for North Quarry represent worst case conditions as due to excavation, the metals in the rock have been made more available by weathering of the rock surfaces. Limestone typically yields the highest metal concentrations, as demonstrated by the information contained in Table 7.

6.3.1 North Quarry

The key water mass balance components and the water quality described for each component is provided in Table 8.

Currently, stormwater enters the North Quarry by running over fractured and weathered rock. In addition, groundwater enters the North Quarry as seeps through fractured and weathered rock. Seeps flow across the weathered rock and have time to dissolve general minerals and metals. While there is no data characterizing the inflowing seepage water, it is conservatively assumed that the chemistry is similar to the current North Quarry water quality. However, once the backfilling commences and the quarry is allowed to gradually flood, it is expected that the quality of the water in the quarry will improve. The existing weathered material will be compacted and covered making it less reactive. In addition, weathering of the quarry walls will slow as the backfill material and water accumulates over it, reducing reactivity and the solubilizing of metals. By the time the backfill reaches 990 ft amsl, it is expected that the groundwater quality inflow to the quarry will return to that typically measured in the groundwater wells (Table 3).

For all constituents considered, the water quality in the North Quarry and in the outflows from the quarry improve once the backfilling activities start. Water quality projections for the North Quarry are as follows:

Constituent		North Quarry Pit Water (Measured and Projected)		Basin Plan Benchmarks (Table 1)	Drinking Water Benchmarks (for comparison)
		Current	After Reclamation		
Antimony	(µg/L)	8.2	1.5 - 2.0	--	6
Arsenic	(µg/L)	4.5	2.5 - 3.0	150 (4d), 340 (1h)	10
Cadmium	(µg/L)	0.53	0.15 - 0.20	1.1 (4d), 3.9 (1h)	5
Copper	(µg/L)	1.5	1.5 - 1.6	9 (4d), 13 (1h)	1,300
Manganese[1]	(µg/L)	21	15 - 20	--	50
Molybdenum	(µg/L)	540	85 - 100	--	--
Nickel	(µg/L)	160	20 - 30	52 (4d), 470 (1h)	100
Selenium	(µg/L)	82	10 - 15	5 (4d), 20 (1h)	50
TDS	(mg/L)	790	500 - 600	450	500
Sulfate	(mg/L)	550	100 - 200	--	250

(1) Concentration projections for manganese are higher than what will be observed because manganese will not behave conservatively as assumed in the projection models. See text in section 6.3.

Detailed plots of projected water quality versus time are provided in Figures 7A through 7B.

Projections of future surface water quality in the runoff from the reclaimed North Quarry area are as follows:

Constituent		North Quarry Runoff (Measured and Projected)		Basin Plan Benchmarks (Table 1)	Drinking Water Benchmarks (for comparison)
		Ongoing Mining	After Reclamation		
Antimony	(µg/L)	5.5 – 6.0	4.5 – 5.0	--	6
Arsenic	(µg/L)	3.5 – 4.0	3.5 – 4.0	150 (4d), 340 (1h)	10
Cadmium	(µg/L)	0.20 – 0.25	0.05 – 0.10	1.1 (4d), 3.9 (1h)	5
Copper	(µg/L)	0.80 – 1.00	0.60 – 0.80	9 (4d), 13 (1h)	1,300
Manganese[1]	(µg/L)	8 - 10	4 - 5	--	50
Molybdenum	(µg/L)	180 - 200	20 - 30	--	--
Nickel	(µg/L)	50 - 60	5 - 10	52 (4d), 470 (1h)	100

Selenium	(µg/L)	25 - 30	2 - 5	5 (4d), 20 (1h)	50
TDS	(mg/L)	300 - 350	100 - 150	450	500
Sulfate	(mg/L)	150 - 200	20 - 30	--	250

(1) Concentration projections for manganese are higher than what will be observed because manganese will not behave conservatively as assumed in the projection models. See text in section 6.3.

Detailed plots of projected water quality versus time are provided in Figures 8A through 8B.

As indicated by these projections, reclamation results in significant improvements to water quality. The quality in both the North Quarry and surface runoff is expected to meet (nickel) or come close to meeting (TDS and selenium) the applicable Benchmarks. The Drinking Water Benchmarks, although not applicable to Permanente Creek surface water, are included to demonstrate that the water quality will not pose a risk to human health if it were to be used for consumption.

6.3.2 South Quarry

The key water mass balance components and the water quality described for each component is provided in Table 9.

Water quality projections for the South Quarry mining, when water accumulates in the pit during backfilling and thereafter, is as follows:

Constituent		South Quarry Pit Water (Projected)		Basin Plan Benchmarks (Table 1)	Drinking Water Benchmarks (for comparison)
		Start of Mining	After Reclamation		
Antimony	(µg/L)	0.2 - 1.0	0.3 - 0.4	--	6
Arsenic	(µg/L)	0.8 - 2.2	2 - 3	150 (4d), 340 (1h)	10
Cadmium	(µg/L)	0.05 -0.1	0.15 - 0.20	1.1 (4d), 3.9 (1h)	5
Copper	(µg/L)	1 - 1.2	1.6 - 1.7	9 (4d), 13 (1h)	1,300
Manganese[1]	(µg/L)	0 - 10	0 - 10	--	50
Molybdenum	(µg/L)	19 - 21	10 - 11	--	--
Nickel	(µg/L)	4 - 5	3 - 4	52 (4d), 470 (1h)	100
Selenium	(µg/L)	8 - 12	1 - 2	5 (4d), 20 (1h)	50
TDS	(mg/L)	400 - 600	500 - 600	450	500
Sulfate	(mg/L)	100 - 140	120 - 140	--	250

(1) Concentration projections for manganese are higher than what will be observed because manganese will not behave conservatively as assumed in the projection models. See text in section 6.3.

Detailed plots of projected water quality in the South Quarry are provided in Figures 9A through 9B.

Projections of future surface water quality in the runoff from the mined and reclaimed South Quarry area are as follows:

Constituent		South Quarry Runoff (Projected)		Basin Plan Benchmarks (Table 1)	Drinking Water Benchmarks (for comparison)
		Start of Mining	After Reclamation		
Antimony	(µg/L)	2 - 4	3 - 4	--	6
Arsenic	(µg/L)	6 - 12	6 - 8	150 (4d), 340 (1h)	10
Cadmium	(µg/L)	0.06 - 0.08	0.06 – 0.08	1.1 (4d), 3.9 (1h)	5
Copper	(µg/L)	0.7 – 0.9	0.7 – 0.8	9 (4d), 13 (1h)	1300
Manganese[1]	(µg/L)	5 - 6	4 - 5	--	50
Molybdenum	(µg/L)	15 - 18	15 - 16	--	--
Nickel	(µg/L)	3 - 4	3 - 4	52 (4d), 470 (1h)	100
Selenium	(µg/L)	3 - 6	3 - 4	5 (4d), 20 (1h)	50
TDS	(mg/L)	80 - 120	80 - 120	450	500
Sulfate	(mg/L)	20 - 30	20 - 25	--	250

(1) Concentration projections for manganese are higher than what will be observed because manganese will not behave conservatively as assumed in the projection models. See text in section 6.3.

Detailed plots of projected water quality versus time are provided in Figures 10A through 10B.

As with the North Quarry, reclamation in the South Quarry results in significant improvements to water quality. The initial quarry water and runoff quality is expected to be better than for North Quarry. After reclamation, South Quarry water quality is expected to meet all applicable Benchmarks.

7.0 MINE RECLAMATION RECOMMENDATIONS

Mining and reclamation under the Project are expected to progressively improve surface water quality in Permanente Creek, especially following Phase 2 when significant areas of exposed limestone are covered and reclaimed in the North Quarry. However, in recognition of the uncertainties associated with the predictions of future water quality, as described in Section 6.0 above, it is recommended that a monitoring and verification program be implemented to verify the predictions with actual field data as mining proceeds. In order to

maximize water quality improvements, prudent water management measures are recommended for the active mining period.

The sections below describe the proposed monitoring and verification program and the recommended water management measures. The final Section 7.3 discusses how these programs and plans can be implemented.

7.1 Monitoring and Verification Programs

It is recommended that the following program be implemented during mining operations. This monitoring program focuses on mining in the North Quarry and the South Quarry and does not address any general environmental monitoring that may be required in the quarries.

- Collect annual quarry water samples and analyze for general water chemistry and dissolved metals.
- Perform quarterly electrical conductivity and pH measurements of the quarry water.
- Measure and record daily volumes of any quarry water that is removed.
- Conduct annual seep surveys in March or April of each year within each quarry. Any seeps identified should be sampled for general water chemistry and minerals and dissolved metals and the magnitude of the seep should be estimated.

It is recommended that the above information, plus available rainfall data, be used to review and refine the water quality projections contained in this report on an interval of approximately every three years, or as necessary. The above data should be used to re-evaluate the water balance components such as runoff and groundwater inflow and the water quality associated with these.

Based on the results of any refined water balance and water quality projections, the water management procedures described below should also be reviewed and refined as necessary.

7.2 Water Management Measures

The following water management measures are recommended for the North Quarry and the South Quarry and the ore and overburden handling. These measures are in addition to the usual measures undertaken to eliminate suspended sediments from any water that is to be removed from a quarry, i.e. internal sediment basins, sump intake filters, etc.

- In order to minimize the uptake of dissolved metals from the limestone, quarry drainage controls should be implemented to separate runoff from the breccia, graywacke, and greenstone materials. To the extent possible, drainage of the former should be diverted directly to sediment control facilities and natural surface drainages. The mining plan for South Quarry already incorporates these measures (Chang, 2010).

- Wherever possible, surface drainage should be placed around newly disturbed limestone areas and limestone stockpiles in the quarry areas. This will avoid excessive water contact with exposed limestone by run-on from upgradient areas.

- Where limestone materials are disturbed or stockpiled, minimize water ponding which would increase contact and contact time between rainfall and limestone materials. Grade out hollows and compact surfaces with equipment (such as dozers), as necessary.

Reclamation design also should incorporate a subsurface outflow drain system, in order to control the maximum level of groundwater in the quarries and to promote diffusion and infiltration of excess groundwater into the Permanente Creek catchment area.

7.3 Implementation of Monitoring and Water Management Plans

The facility is subject to the General Industrial Stormwater Permit and Lehigh manages the water associated with its quarry operations pursuant to a Stormwater Pollution Prevention Plan (SWPPP). In addition to the recommendations included in Sections 7.1 and 7.2 above, Lehigh is currently working with the RWQCB to evaluate its existing stormwater best management practices (BMPs), enhance the existing BMPs where needed, and develop new BMPs to control the transport of sediment and metals into the North Quarry. As part of that effort, Lehigh will add the recommendations included in Sections 7.1 and 7.2 above to the SWPPP with the RWQCB's concurrence. In addition, Lehigh will conduct additional sampling, further evaluate the sources of constituents in waters associated with the operations and confirm the conclusions of this report. With input from the RWQCB, Lehigh will revise its SWPPP and monitoring program as required by General Permit Section C.3.a. Based on the findings of the BMP assessment at North Quarry, additional BMPs may be adopted which will apply, as appropriate, to the South Quarry.

Notes:
Shading indicates an exceedance of the most stringent Benchmark.
[1] MCL ("maximum contaminant level") is the primary drinking water standard;
SMCL ("secondary maximum contaminant level") is the secondary drinking water standard based on aesthetics and odors.
ND = Not detected at the specified detection limit.
When an ND was included in the calculation of an average value, it was assumed to be one half the detection limit.
If all samples were ND, then the lowest detection limit was retained.

TABLE 8
NORTH QUARRY WATER QUALITY PARAMETERS

Water Balance Component	Rock type	Water Quality										Rationale
		Antimony (µg/L)	Arsenic (µg/L)	Cadmium (µg/L)	Copper (µg/L)	Manganese (µg/L)	Molybdenum (µg/L)	Nickel (µg/L)	Selenium (µg/L)	TDS (mg/L)	SO_4 (mg/L)	
WMSA Runoff	Various	0.86	1.3	0.06	1.2	14	120	3.4	29	900	550	WMSA runoff quality –Table 7
Quarry Walls	Greenstone & graywacke	4.53	3.6	0.06	0.64	3.8	14.6	2.9	1.2	108	15	CAM WET tests (average for all tests) – Table 6
Quarry Walls	Limestone	8.2	4.5	0.53	1.5	21	540	160	82	790	550	North Quarry Water – Table 7
Infiltration through quarry backfill	Greenstone and graywacke	4.53	3.6	0.06	.64	3.8	14.6	2.9	1.2	108	15	CAM WET tests (average for all tests)
Groundwater Inflow	Various, mainly limestone During Phase 1 prior to backfilling	8.2	4.5	0.53	1.5	21	540	160	82	790	550	North Quarry Water – Table 7
	Gradual improvement during backfilling	Linear interpolation										N/A
	At the end of the backfill to the 990 level during Phase 3	0.23	2.34	0.06	1.66	21[1]	10.8	4.1	0.7	616	143	Average groundwater quality from Table 3

[1] Manganese value based on North Quarry Pit water.

TABLE 9
SOUTH QUARRY WATER QUALITY PARAMETERS

Water Balance Component	Rock type	Water Quality										Rationale
		Antimony (µg/L)	Arsenic (µg/L)	Cadmium (µg/L)	Copper (µg/L)	Manganese (µg/L)	Molybdenum (µg/L)	Nickel (µg/L)	Selenium (µg/L)	TDS (mg/L)	SO_4 (mg/L)	
Quarry Walls	Greenstone & graywacke	4.53	3.6	0.06	0.64	3.8	14.6	2.9	1.2	108	15	CAM WET tests (average for all tests) – Table 6
Quarry Walls	Limestone	0.24	20.7	0.08	1.17	8.38	20.5	4.5	10.7	81.8	45.2	Wall washing average – Table 7
Infiltration through quarry backfill	Greenstone and graywacke	4.53	3.6	0.06	0.64	3.8	14.6	2.9	1.2	108	15	CAM WET tests (average for all tests) - Table 6
Groundwater Inflow	Various, mainly limestone During Phase 1 prior to backfilling	0.24	20.7	0.08	1.14	8.38	20.5	4.5	10.7	616	143	Wall washing (average) for metals – Table 7 Average groundwater quality from Table 3 for TDS and sulfate
	Gradual improvement during backfilling	Linear interpolation										N/A
	At the end of the backfill to the 990 level during Phase 3	0.23	2.34	0.06	1.66	8.38[1]	10.8	4.1	0.7	616	143	Average groundwater quality from Table 3 Wall washing (average) for manganese – Table 7

[1] Manganese value based on wall washing average. Concentration projections for manganese are likely higher than what will be observed because it precipitates under oxidizing conditions.

Appendix D

Water Balance and Water Quality Calculations

Appendix D.1.1

D.1.1 North Quarry Reclamation Water Quality Projections

North Quarry Pit Lake Water Budget

Inflows and Outflows	Parameters		Value	Units	Description and Rationale				
Precipitation	Precipitation		1.85	ft/yr	Los Altos climate station, direct precip on wasterock backfill area is based on monthly precip data				
			Phases						
			Initial	1	2	3	4	5	Long Term
Quarry Backfilling Areas	**Surface Water Drainage to Pit**								
	Quarry Area (Greenstone/Greywacke)		4,900,000	6,700,000	9,000,000	-	-	-	-
	Quarry Area (Limestone)		7,000,000	7,000,000	4,800,000	-	-	-	-
	WMSA		3,600,000	1,800,000	-	-	-	-	-
	Surface Infiltration to Pit (Through backfill)								
	Undrained Backfill (No Surface Outlet)		-	-	1,800,000	-	-		
	Drained Backfill (With Surface Outlet)					800,000	800,000	800,000	800,000
	Spill Elevation		990.00	ft amsl	Based on mine plan				
	Bottom of Pit		440.00	ft amsl	Based on end of Phase 1 for South Quarry mine plan				
Groundwater Capture	Initial		371	gpm	MODFLOW model results for Phase 1, maximum excavation condition				
			2,181,181	cu ft/mo					
	At Spill Elevation		80	gpm	MODFLOW model results for ultimate condition				
			470,336	cu ft/mo					
Date Quarry Filling Starts	**1/1/2023**								
Assumptions	The pit is backfilled incrementally over a 4-year period, from 440 ft amsl to the spill-over elevation of 990 ft amsl								
	Backfill material has a porosity of 30-percent.								
	Surface runoff is only within the capture area of the pit and is based on water year 2009 data								
	Groundwater inflow into the pit varies by month and diminshes as the backfill increases								
	Precipitation directly infiltrates to the water table within the area of the backfill.								
	Evaporation of the pit lake is only applied when the cumulative volume of water in the pit is greater than the cumulative volume of void spaces within the backfill (based on 30-percent porosity)								
	The water level in the pit is dependent on the total cumulative volume of the backfill up to the spill-over elevation.								

Phase	Year	Month	Total Months	Date	Quarry Area (Greenstone/Greywacke)	Quarry Area (Greenstone/Greywacke)	Quarry Area (Limestone)	Quarry Area (Limestone)	WMSA	WMSA	Groundwater Inflow	Undrained Backfill (No Surface Outlet)	Undrained Backfill (No Surface Outlet)
					sq ft	cu ft	sq ft	cu ft	sq ft	cu ft	cu ft	sq ft	cu ft

Appendix D.1.2

D.1.2 North Quarry Runoff Water Quality Projections

North Quarry Runoff Water Budget

Inflows and Outflows	Parameters		Value	Units	Description and Rationale				
Precipitation	Precipitation		1.85	ft/yr	Los Altos climate station, direct precip on wasterock backfill area is based on monthly precip data				
			Phases						
			Initial	1	2	3	4	5	Long Term
Quarry Backfilling Areas	**Surface Water Drainage to Pit**								
	Quarry Area (Greenstone/Greywacke)					11,700,000	12,800,000	14,500,000	14,500,000
	Quarry Area (Limestone)					3,900,000	2,800,000	200,000	200,000
	WMSA					-	-	-	-
	Surface Infiltration to Pit (Through backfill)								
	Undrained Backfill (No Surface Outlet)		-						
	Drained Backfill (With Surface Outlet)								
	Spill Elevation		990.00	ft amsl	Based on mine plan				
	Bottom of Pit		440.00	ft amsl	Based on end of Phase 1 for South Quarry mine plan				
Groundwater Capture	Initial		371	gpm	MODFLOW model results for Phase 1, maximum excavation condition				
			2,181,181	cu ft/mo					
	At Spill Elevation		80	gpm	MODFLOW model results for ultimate condition				
			470,336	cu ft/mo					
Date Quarry Filling Starts		**1/1/2023**							
Assumptions	The pit is backfilled incrementally over a 4-year period, from 440 ft amsl to the spill-over elevation of 990 ft amsl								
	Backfill material has a porosity of 30-percent.								
	Surface runoff is only within the capture area of the pit and is based on water year 2009 data								
	Groundwater inflow into the pit varies by month and diminshes as the backfill increases								
	Precipitation directly infiltrates to the water table within the area of the backfill.								
	Evaporation of the pit lake is only applied when the cumulative volume of water in the pit is greater than the cumulative volume of void spaces within the backfill (based on 30-percent porosity)								
	The water level in the pit is dependent on the total cumulative volume of the backfill up to the spill-over elevation.								

Phase	Year	Month	Total Months	Date	Quarry Area (Greenstone/Greywacke)	Quarry Area (Greenstone/Greywacke)	Quarry Area (Limestone)	Quarry Area (Limestone)	WMSA	WMSA	Groundwater Inflow (Zerod out, included in pit water budget)	Undrained Backfill (No Surface Outlet)	Undrained Backfill (No Surface Outlet)

Date Quarry Filling Starts	**1/1/2036**							
Assumptions	The pit is backfilled incrementally over a 4-year period, from 440 ft amsl to the spill-over elevation of 990 ft amsl							
	Backfill material has a porosity of 30-percent.							
	Surface runoff is only within the capture area of the pit and is based on water year 2009 data							
	Groundwater inflow into the pit varies by month and diminshes as the backfill increases							
	Precipitation directly infiltrates to the water table within the area of the backfill.							
	Evaporation of the pit lake is only applied when the cumulative volume of water in the pit is greater than the cumulative volume of void spaces within the backfill (based on 30-percent porosity)							
	The water level in the pit is dependent on the total cumulative volume of the backfill up to the spill-over elevation.

		58,792	cu ft/mo					
	Unmined	-	gpm					
		1,122	ft amsl	calculated				
Date Quarry Filling Starts	**1/1/2036**							
Assumptions	The pit is backfilled incrementally over a 4-year period, from 440 ft amsl to the spill-over elevation of 990 ft amsl							
	Backfill material has a porosity of 30-percent.							
	Surface runoff is only within the capture area of the pit and is based on water year 2009 data							
	Groundwater inflow into the pit varies by month and diminshes as the backfill increases							
	Precipitation directly infiltrates to the water table within the area of the backfill.							
	Evaporation of the pit lake is only applied when the cumulative volume of water in the pit is greater than the cumulative volume of void spaces within the backfill (based on 30-percent porosity)							
	The water level in the pit is dependent on the total cumulative volume of the backfill up to the spill-over elevatic
